Weather Observations at the Agricultural Science Center at Tucumcari, 1905-2002

Rex E. Kirksey, Leonard M. Lauriault, and Patricia L. Cooksey¹

SUMMARY

Based on annual averages, weather in the Tucumcari, N.M. area is pleasant and mild. The area is characterized as having a semiarid, continental climate with seasonal temperature changes, low humidity and generally clear skies. Annual precipitation averages 15.91 inches. Mean monthly temperatures range from 78.9°F in July to 38.1°F in January. However, averages don't tell the whole story. Precipitation in the area is sporadic and variable. Most precipitation is received in the form of brief, sometimes heavy thunderstorms, which occasionally are accompanied by hail and damaging winds. Annual precipitation has ranged from a low of 6.13 inches in 1934 to a high of 34.96 inches in 1941. Although average daily maximum temperatures in the summer are in the low 90s, temperatures of 100°F or above were recorded on 40 different days in 1980. In an average year, freezing temperatures occur on 30% of all days, and there is one day with subzero temperatures. The lowest recorded temperature at Tucumcari was -22°F on Jan. 13, 1963. The highest temperature, 109°F, was recorded on June 25, 1990. The growing season, defined as the number of days between the last occurrence of 32°F in the spring and the first occurrence of 32°F in the fall, averages 189 days. But the growing season has been as short as 136 days and as long as 222 days.

Annual averages present a generalized overview of weather conditions, but they fail to recognize the variability and uncertainty of weather conditions in the Tucumcari area. To better understand the area's weather dynamics, this report contains a summary of weather observations at Tucumcari from 1905 through 2002.

HISTORY

The first documented weather observations in the Tucumcari area were from a weather station near the Tucumcari Post Office (Williams, 1967). That weather station was on the east side of what is now Second Street, about one-half block south of Main Street. The station was operational from Dec. 16, 1904 until Feb. 28, 1913. Daily observational data from that station are not available, but records of monthly precipitation and average air temperatures have been maintained.

New Mexico State University's Agricultural Science Center at Tucumcari, previously known as the Northeastern Branch Station and the Tucumcari Field Station, is located 3 miles northeast of Tucumcari in Quay County, New Mexico. The center began recording daily precipitation in January 1912. Air temperatures were first recorded on May 26 of that year. Throughout most of 1912 and a couple of months in 1913, precipitation and temperature observations were made at the Tucumcari townsite and at the center. The center's precipitation records for 1912 appear to be complete, but there were a number of missing temperature observations in that year. Therefore, the effective beginning date for the center's daily temperature observations is Jan. 1, 1913. The weather station at the center has remained in continuous operation since its establishment in 1912.

EQUIPMENT

The weather station at the science center is located in an area of native vegetation about 500 feet south of the

¹Agricultural economist, forage agronomist and records technician, respectively, Agricultural Science Center at Tucumcari, Tucumcari, New Mexico.

center headquarters. It is surrounded by a chain-link fence. The weather yard is at an elevation of 4,086 feet, latitude 35°12'N and longitude 103°41'W. It is part of the National Weather Service (NWS) Cooperative Observer Program. Center personnel collect daily weather observations and NWS personnel maintain the station. For most of the station's history, daily observations have been collected at 8 a.m. The exception is the period from Jan. 1, 1953 through March 31, 1981, when the observation time was 5 p.m. Weather observation data are submitted monthly to the National Climatic Data Center, where files from cooperative weather stations throughout the country are maintained. Data files from the center's weather station (Index Number 29-9156-03) are Internet accessible at www.ncdc.noaa.gov/oa/ncdc.html.

The center's weather yard has been at its current location since April 1, 1984. From Jan. 1, 1912 through March 31, 1984, the weather yard was located 349 feet north and 188 feet east of its current location. The weather station was moved away from trees that had grown in close proximity to the initial location. This also accommodated the installation of a Campbell Scientific automated weather station in the same fenced enclosure as the NWS station. Data from that Campbell weather station are not included in this report, but are accessible at weather.nmsu.edu/stations/tucumcar.htm.

Precipitation is measured with a standard 8-inch, nonrecording precipitation gauge, with a one-tenth cross-section area measuring tube. Air temperatures are recorded with standard liquid-in-glass type maximum (mercury-filled bulb) and minimum (alcohol-filled bulb) NWS thermometers. The thermometers are housed in a regulation (medium-sized type, louvered) instrument shelter and are positioned 5 feet above ground level.

A totalizing three-cup anemometer set 2 feet above ground level measures wind movement. From 1918 through 1969, and from 1983 through 2002, daily wind movement was recorded for all months. From 1970 through 1982, daily wind movement was recorded only from April through September.

From 1913 through 1952, evaporation was measured in a sunken circular metal tank. An aboveground Class A cylindrical (10 in. deep and 47 1/2 in. inside diameter) metal pan was installed in 1953. Evaporation readings are taken with a micrometer hook-gauge. Historically, evaporation readings have been taken from April through September. October evaporation readings have been collected since 1993, but they are not included in this report because of the limited number of observations. Maximum and minimum temperatures of the evaporation pan water have been recorded with a Six's thermometer since April 1981, but they are not included in this report.

Maximum and minimum soil temperatures have been recorded since 1977. Soil temperatures are recorded

with a Palmer Soil Thermometer located 4 inches below the bare soil surface.

For this report, records of daily observations at the center were entered in Microsoft Excel spreadsheets, and monthly averages and totals were calculated and combined with summary data from the Tucumcari town-site weather station. Considerable effort has been expended to ensure the data's accuracy. In some instances, the data reported herein will differ slightly from earlier publications of the center's weather observations (Burnham, 1954; Williams, 1967; Williams, 1977; and Kirksey, 1987). The data in this report should be the most accurate. To detect changes in weather patterns over time, selected time series data were analyzed using the REG procedure of SAS (SAS Inst., 1996). Differences are considered significant at $P < 0.05$.

PRECIPITATION

Annual precipitation at Tucumcari from 1905 through 2002 averaged 15.91 inches (table 1 and table A1). Although there has been considerable interest and concern about drought and low precipitation amounts in recent years, there has been only a very slight, nonsignificant ($P = 0.92$) decrease (-0.002 in/yr) in annual precipitation since 1905 (fig. 1). Year-to-year variability ($SD = 5.02$ in.) is much greater than the cumulative effect of any downward trend. Another perception that precipitation has become more variable in recent years is not supported by observations at Tucumcari. For the first 49 years of observation (1905-1953), annual precipitation averaged 15.92 ± 5.74 inches, while average precipitation during the most recent 49-year period averaged 15.91 ± 4.25 inches. For the 10 most recent years, precipitation has been greater and less variable (16.49 ± 3.66 in.) than the previous 88 years (15.85 ± 5.17 in.) (fig. 1). The greatest amount of precipitation in one year was 34.96 inches in 1941; the least was 6.13 inches in 1934 (table 1). Precipitation has been below average in 57 of the 98 years of observation (fig. 1). In four of these years, annual precipitation was less than 10 inches. Annual precipitation in excess of 20 inches has been recorded in 13 years.

Seventy-four percent of the annual precipitation at Tucumcari falls between April 1 and September 30 (table 1). Most of it is in the form of brief, but sometimes heavy, thunderstorms that are occasionally accompanied by hail. Hail seems to strike localized areas and can cause considerable damage, depending on location, severity of the storm and the time of year. On rare occasions, thunderstorms in the Tucumcari area are accompanied by tornadoes. The possibility of these devastating phenomena warrants close observation of weather conditions during periods of inclement weather.

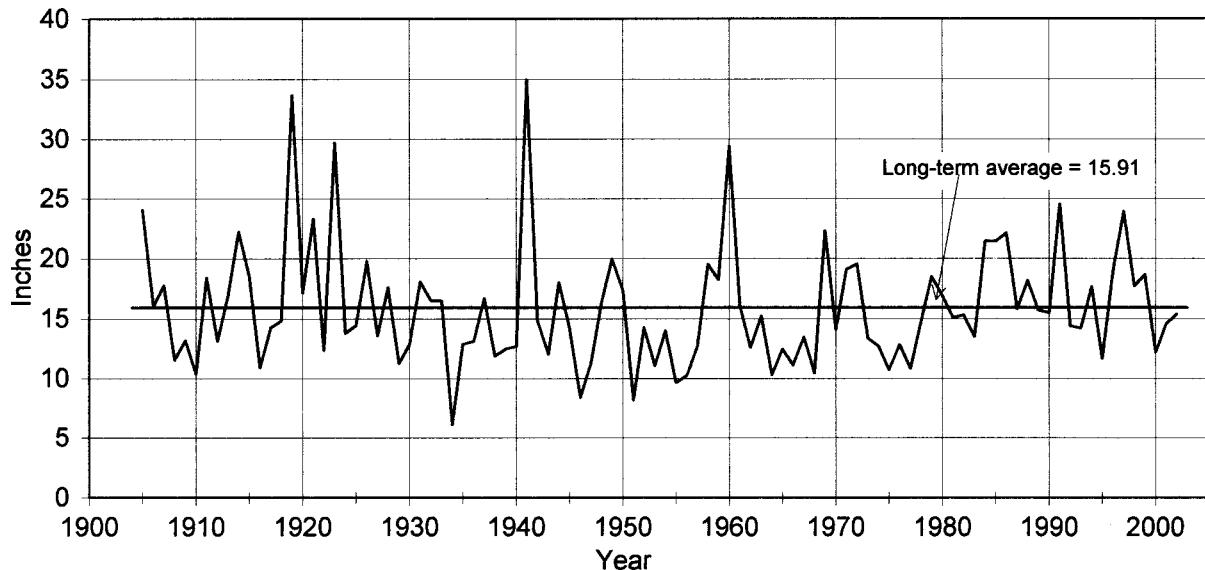

Figure 1. Annual and long-term average precipitation, Tucumcari, N.M., 1905-2002.

August and July, the wettest months, receive an average of 2.69 and 2.63 inches of precipitation, respectively, and account for one-third of the annual rainfall at Tucumcari (table 1). January, the driest month, receives an average of only 0.37 inches of precipitation.

The greatest monthly precipitation, 11.28 inches, was recorded in July 1950. Six percent of all months since 1905 have received no measurable precipitation. The greatest amount of precipitation recorded in a 24-hour period was 4.41 inches on June 20, 1971 (table 2). Precipitation amounts in excess of 4 inches have not been recorded on any other date. Precipitation has been recorded at the center on 21% of all days since 1912 (average = 75 d/yr). However, much of this precipitation is of little or no benefit. More than half of the precipitation observations at Tucumcari have been daily amounts of 0.10 inch or less. A frequency distribution of daily precipitation amounts, by month, is shown in table 3.

The center's snowfall records are incomplete. Observations prior to 1922, and for the years 1951 through 1958, are missing. Snow often falls during the winter, but seldom remains on the ground for more than a few days. The most snow recorded in one winter was 61.5 inches in the winter of 1982-1983. The least amount is 1.5 inches, which was recorded during the winter of 1945-1946. Snow has been recorded as early as Oct. 8 and as late as May 18.

TEMPERATURE

The Tucumcari area has a semiarid, continental climate, with distinct seasonal temperature changes and a wide range in daily temperatures (fig. 2). The annual mean temperature at Tucumcari for the years 1905 through 2002 was 58.2°F (table 4). Mean monthly temperatures range from a high of 78.9°F in July to a low of 38.1°F in January.

Daily temperatures usually are at a minimum around sunrise and reach a maximum in late afternoon. Summer temperatures are warm. Average daily maximum temperatures exceed 90°F from June 14 through Aug. 23 (fig. 2). Average minimum temperatures during this time are in the low to mid 60s°F. Average daily maximum temperatures during December and January are in the mid to low 50s, except for a few days around the first of January when average maximum daily temperatures dip into the upper 40s (fig. 2). Average daily minimum temperatures are below freezing from Nov. 19 through March 9. Frequency distributions of daily maximum and minimum temperatures are shown in tables 5 and 6.

Monthly extreme temperatures and their dates of occurrence are shown in table 7. The highest temperature ever recorded at Tucumcari, 109°F, occurred on June 25, 1990. The lowest temperature, -22°F, was recorded on Jan. 13, 1963. Average monthly maximum, minimum and mean temperatures, by year, are shown in tables A2-A4.

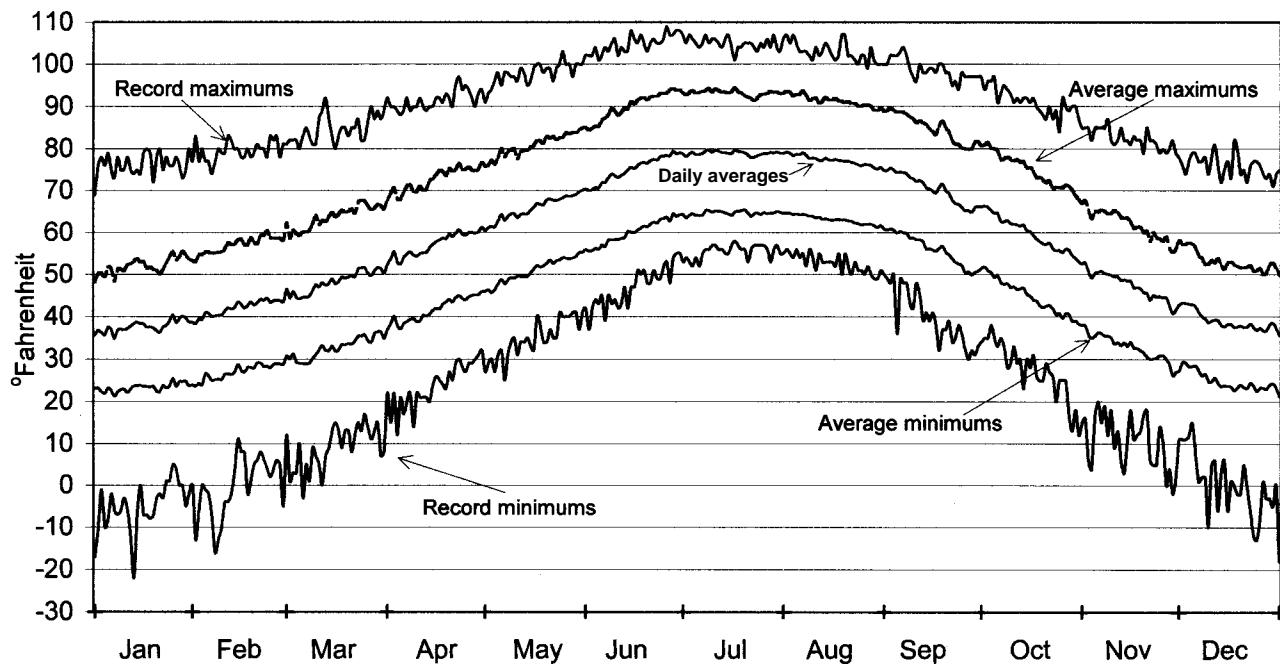

Figure 2. Daily temperature data, Agricultural Science Center at Tucumcari, N.M., 1913-2002.

Statistical analysis of temperature data for the period 1913 through 2002 reveals there has been a significant linear increase in maximum, mean and minimum temperatures (+0.031, +0.020 and +0.009°F/yr, respectively). Maximum, minimum and mean annual temperatures and associated trend lines are shown in fig. 3.

SPRING AND FALL FREEZE DATES AND GROWING SEASON

Annual information on the date of the last spring and first fall temperatures of 26°F, 28°F, 30°F and 32°F is presented in table A5. The average length of the growing season, the number of days between the last occurrence of 32°F in the spring and the first occurrence of 32°F in the fall, is 189 days. The shortest growing season, with only 136 days, occurred in 1945. The longest, 222 days, was in 1989. The average date of the last 32°F reading in the spring is April 17. The last freezing temperature in spring has occurred as early as March 24 and as late as May 15. The average date of the first 32°F reading in the fall is Oct. 23. The first freezing temperature in fall has been recorded as early as Sept. 17 and as late as Nov. 19 (table A5). For the period 1913 through 2002, there has been no significant change in the dates of the last spring freeze ($P = 0.06$), first fall freeze ($P = 0.98$) or length of the growing season ($P = 0.14$). Figs. 4 and 5 present the historical frequency of last spring and first fall freeze events.

HEAT UNITS

Heat units, or growing degree days (GDD), are used to predict the growth and development of many crops, including cotton, corn and alfalfa. Different crops use different temperature bases for heat unit calculations. Cotton uses a base temperature of 60°F; corn uses a base temperature of 50°F; and temperatures of 32°F and 41°F are used as bases for alfalfa. Heat units in this report are calculated on a 60°F base.

Daily heat unit accumulations are calculated to be the difference between the average daily temperature and the base temperature, in this case 60°F. No heat units accumulate if the difference between the average temperature and the 60°F temperature base is zero or negative. Average daily and seasonal (May-October) heat unit accumulations are presented in table A6. Average seasonal accumulation at Tucumcari is 2,220 heat units. The highest accumulation of 2,837 heat units occurred in 2000; the lowest accumulation, 1,747 heat units, was in 1941.

NMSU Extension Guide A-227 (Ball, 1998) indicates approximately 1,900 to 2,600 GDD are required for a cotton crop to reach harvest maturity. Based on a May 15 planting date, the average heat unit accumulation for a cotton crop in the Tucumcari area is 2,148 heat units (seasonal average of 2,220 heat units less the 72 units accumulated prior to May 15). With a May 15 planting date, heat unit accumulations at Tucumcari have been below the 1,900 GDD threshold in 9% of all

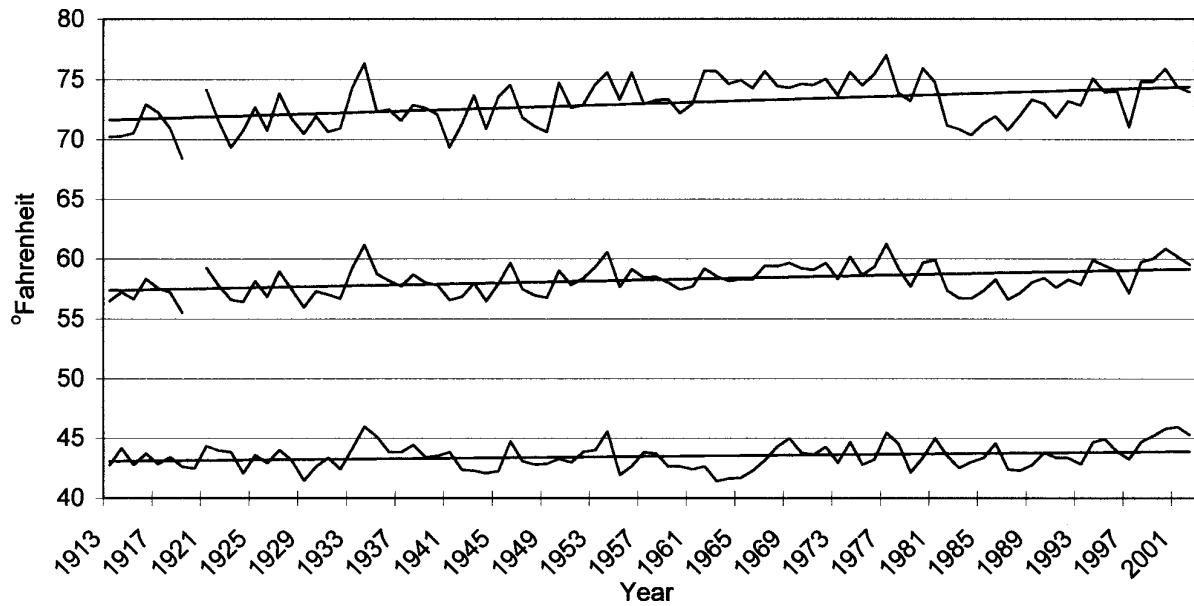

Figure 3. Maximum, minimum and mean annual temperatures and their trend lines, Agricultural Science Center at Tucumcari, N.M., 1913-2002.

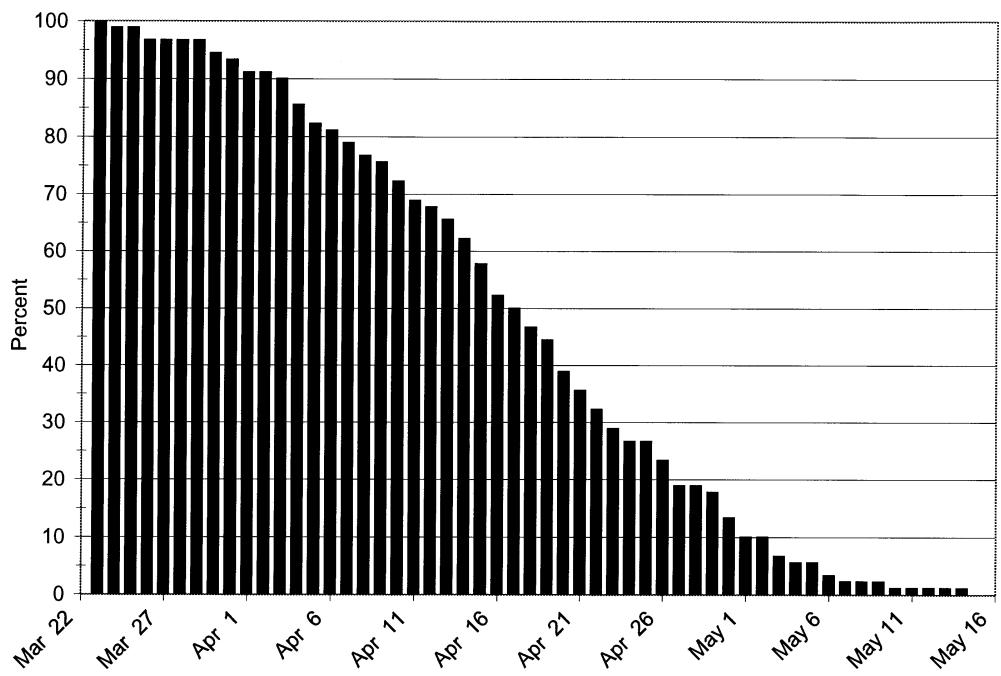

Figure 4. Percentage of years with last spring freeze (32°F or below) occurring after specific dates, Agricultural Science Center at Tucumcari, N.M., 1913-2002.

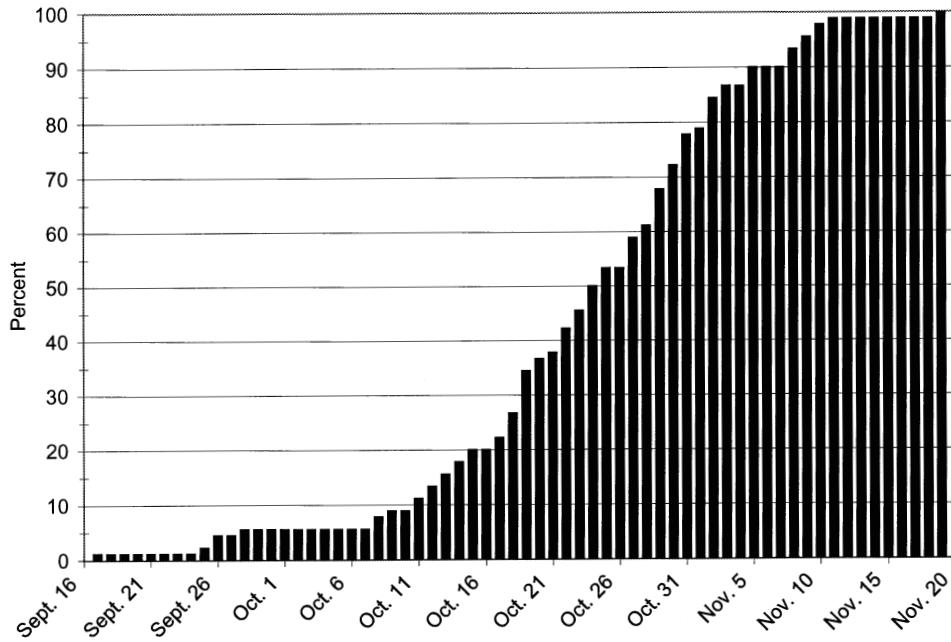

Figure 5. Percentage of years with first fall freeze (32°F or below) occurring before specific dates, Agricultural Science Center at Tucumcari, N.M., 1913-2002.

years, and below the 2,000 GDD level in 24% of the years for which data are available.

WIND

Average wind velocities are shown in table A7. Spring is the windiest time of the year. In those years for which year-round wind measurement data exist, April, March and May had the highest average wind speeds (5.8, 5.6 and 5.2 mph, respectively). August is the calmest month with an average wind speed of 3.3 mph for the 85-year observation period (table A7).

There was a significant linear decline in average annual wind speed (-0.047 mph/yr) over the period 1918 to 1983. Although the cause of the decline cannot be determined, the growth of windbreaks and ornamental trees in the vicinity of the weather yard undoubtedly contributed to the reduction. In 1984, movement of the weather yard away from the center headquarters resulted in a significant increase (1.12 mph) in average annual wind speeds. Following the move, there has been an increase (0.03 mph/yr) in average annual wind speeds. The wind speeds reported herein are recorded at a height of 2 feet, in a somewhat protected area of natural vegetation. These data are probably not representative of field conditions in the Tucumcari area, but they can be useful in evaluating seasonal and annual trends in wind movement.

EVAPORATION

Evaporation from the free water surface of a raised evaporation pan averages 0.38 inches/day for April through September. Average cumulative evaporation during this period is 69.71 inches (table A8). This is roughly six times the amount of precipitation received during the same period.

There has been no significant ($P=0.17$) linear change in evaporation during the 90 years of observation. However, changing from a sunken evaporation pan to an aboveground pan increased average evaporation rates by an average of 17.14 inches per year.

SOIL TEMPERATURE

Monthly average maximum and minimum soil temperatures, 4 inches below the soil surface, are shown in tables A9-A10. Soil temperatures are lowest in January and highest in July.

There has been a significant linear decrease (-0.11°F/yr) in annual mean maximum soil temperatures and no significant change ($P = 0.24$) in annual minimum soil temperatures for the 26-year observation period. Minimum soil temperatures are used frequently as a guideline for determining optimal planting dates. Daily and 10-day average minimum soil temperatures for March, April and May are shown (table 8).

TEMPERATURE CALENDAR

Average daily maximum and minimum temperatures and daily temperature extremes are of interest to many local residents. Appendix B contains a temperature calendar for Tucumcari. The calendar shows average maximum and minimum temperatures by date, and highest and lowest temperature extremes for each date and the year in which the record temperature occurred. All temperatures are in degrees Fahrenheit.

¹Growing Season = Number of days between the last occurrence of 32°F in the spring and the first occurrence of 32°F in the fall.

²Killing Frost Free Days = Number of days between the last occurrence of 28°F in the spring and the first occurrence of 28°F in the fall.
