The 2021 New Mexico Alfalfa Variety Test Report

Leonard Lauriault, Ian Ray, Chris Pierce, Koffi Djaman, Robert Flynn, Mark Marsalis, Charles Havlik, Gasper Martinez, and Margaret West¹

Introduction

In 2021, 135,000 acres of alfalfa (*Medicago sativa*) were in production in New Mexico, which was a 20,000 acre decrease from 2020. Hay production was estimated at 689,000 tons. At a 2021 average of \$225 per ton (down from \$231 per ton in 2020), estimated gross returns from alfalfa hay produced in 2021 will total nearly \$155 million, which is a 2.6% increase from 2020. Besides its value for hay, alfalfa also is the legume of choice in irrigated perennial pastures. Whether used as pasture or hay, the value of alfalfa to New Mexico is greatly magnified by its contribution to livestock production and receipts from the sale of meat, milk, and other products generated by livestock enterprises.

Choosing a good alfalfa variety is a key step in establishing a highly productive stand of alfalfa, whether for hay or pasture. Differences between the highest- and lowest-yielding varieties in established irrigated tests included in this report ranged from 0.60 to 3.06 tons per acre in 2021. If sold as hay, this translates to a potential difference in returns of \$135 to \$689 per acre due to variety, or an increase of at least \$18 million for the industry in 2021 alone.

This report, which is a collaborative effort of New Mexico State University scientists at agricultural science centers throughout the state, provides yield data for alfalfa varieties included in yield trials in New Mexico. While consistently high yields compared to other varieties over a number of years and locations within a region is the best indication of varietal adaptation and persistence, other factors should be considered in the variety selection process (see NMSU's Cooperative Extension Service Circular 654, Selecting alfalfa varieties for New Mexico). In addition to fall dormancy and winter hardiness, high levels of pest resistance are critical to protecting an alfalfa stand for long-term production. Alfalfa grown in New Mexico should have at least a resistant (R) rating for bacterial wilt, Fusarium wilt, anthracnose, Phytophthora root rot, spotted alfalfa aphid. blue alfalfa aphid, pea aphid, stem nematode, and southern rootknot nematode. Seed quality also should be high. Selecting an alfalfa variety based on seed cost is a gamble producers often lose. To be assured of achieving a long-lasting, highly productive stand, buy either certified or Plant Variety Protected (PVP) seed, which guarantees the genetics and performance. The best choice of seed of any variety is one that was treated with a fungicide and nitrogen-fixing bacteria before it was bagged.

Description of Tests

Replicated alfalfa variety tests included in this report were conducted under research controls at NMSU's Agricultural Science Centers at Las Cruces (2019, full and summer terminated irrigation), Los Lunas (2019), Tucumcari (2018), and Farmington (2018 and 2020). Weather data for 2021 and the long-term averages from all locations are presented in Table 1.

Yield data (on a dry matter basis) are presented in Tables 2-7 Varieties are listed in order from highest to lowest average annual production. Yields are given by cutting for 2021 and by year for each production year. Statistical analyses were performed on all alfalfa yield data (including experimental entries) to determine if the apparent differences are truly due to variety or just to chance. The variety with the highest numerical yield in each column is marked with two asterisks (**), and those varieties not significantly different from that variety are marked with one asterisk (*). Those are the varieties from which to make an initial selection. Otherwise, to determine if two varieties are truly different, compare the difference between the two varieties to the Least Significant Difference (LSD) at the bottom of the column. If the difference is equal to or greater than the LSD, the varieties are truly different in yield when grown under the conditions at a given location. If NS is given for the LSD, there was no statistical difference between the highest and lowest yielding varieties. The Coefficient of Variation (CV), which is a measure of the variability of the data, is included for each column of means. Low variability (<20 percent) is desirable, and increased variability within a study results in higher CVs and larger LSDs. There might be a difference between previously published data and the data given in this publication for the same tests because of differences in the programs used for statistical analysis.

Table 8 summarizes information about proprietors, Roundup Ready genetics, fall dormancy, winter survival (measured in the northern United States), pest resistance, and yield performance across years and locations for all varieties currently included in NMSU's alfalfa variety testing program. For information about other varietal characteristics, such as grazing, salt, or traffic tolerance or GMO traits besides Roundup Ready® genetics, check the National Alfalfa and Forage Alliance website for the Alfalfa Variety Leaflet (https://www.alfalfa.org/varietyLeaflet.php). In Table 8, varieties are listed alphabetically by fall dormancy category. As in the data tables, the variety with the highest numerical yield in each column is marked with two asterisks (**), and those varieties not significantly different from that variety are marked with one asterisk (*). Remember good performance across several years and locations is the best indicator of broad adaptation, pest resistance, and persistence.

Seed labeled "common," "variety not stated," or "variety unknown", particularly that from other states, is of unknown genetic background and may or may not have the necessary disease or insect resistance. New Mexico Common and African Common seed used in all tests throughout the state has come from the same supplier and seed fields in New Mexico. Seed purchased from other dealers may or may not be of the same quality and performance.

Summary

Consistent production of high alfalfa yields is the result of selecting good varieties and implementing good management techniques. Soil fer-

¹Forage Crop Management Scientist and Superintendent, NMSU Rex E. Kirksey Agricultural Science Center at Tucumcari; Alfalfa Breeder, NMSU, Las Cruces; Forage Research Scientist, NMSU, Las Cruces; Agronomist, NMSU Agricultural Science Center at Farmington; Extension Agronomist and Superintendent, NMSU Agricultural Science Center at Artesia; Extension Forage Specialist and Superintendent, NMSU Agricultural Science Center at Los Lunas; Senior Research Assistant, NMSU Agricultural Science Center at Los Lunas; Research Assistant, NMSU Rex E. Kirksey Agricultural Science Center at Tucumcari; and Agricultural Research Scientist, NMSU Agricultural Science Center at Farmington;, respectively.

tility should be maintained at recommended levels based on soil tests, irrigation should be properly applied, weeds and insects should be controlled using appropriate cultural and/or chemical methods, and harvest management should allow sufficient time to restock root energy prior to winter. For dormant (FD 1 to 3) and semidormant (FD 4 to 6) varieties, a 6-week rest period before a dormancy-inducing freeze (27°F) is recommended to allow plants to replenish root reserves for winter survival and initiate spring growth, after which harvesting might be done either mechanically or by grazing. Non-dormant (FD 7 to 9) varieties also might benefit from this rest period. Removing fall growth is beneficial to reducing weevil populations the following year as eggs are laid in and overwinter in stems. Harvesting established stands at early bloom would result in 3 to 5 cuttings per year before initiation of the rest period in most areas of New Mexico. More dormant varieties might not produce yields that can be baled during the rest period; however, these can still be grazed. For additional information about alfalfa management, refer to the other NMSU Agricultural Experiment Station and Cooperative Extension Service publications listed in Table 9.

Acknowledgements

The authors express appreciation to the following for their significant contribution to The New Mexico Alfalfa Variety Testing Program by helping with planting, maintaining, harvesting, or other data collection, and data entry: Dallen Begay, Jason Box, Patty Cooksey, Josh Foster, Lorenzo Gallegos, Ryan Garcia, Christopher Hill, Jared Jennings, Shane Jennings, Jonah Joe, Martin Lopez, Ruben Pacheco, Tom Place, Dennis Price, Patricia Cooksey, Franklin Jason Thomas, and the staff at University Marketing and Communications who make publications such as this possible. Salaries and research support were provided by state and federal funds appropriated to the New Mexico Agricultural Experiment Station. Federal funds included those appropriated through the Hatch Act of 1887.

[†]Data were detrended using nearest neighbor analysis and analyzed using analysis of variance.

No harvests were taken in 2019 due to harvesting equipment and irrigation system failures; Irrigation system failures also occurred in 2020 that were exacerbated by parts availability is-sues due to COVID-19. 2020 Harvest dates: 13-Jul and 21-Oct.

^{**}Highest numerical value in the column.

^{*}Not significantly different from the highest numerical value in the column based on the 5% LSD.

NS means that there were no significant differences between the varieties within that column at the 5% level.

New Mexico State University BE BOLD. Shape the Future.

The College of Agricultural, Consumer and Environmental Sciences is an engine for economic and community development in New Mexico, improving the lives of New Mexicans throughacademic, research, and Extension programs.

New Mexico State University is an equal opportunity/affirmative action employer and educator. NMSU and the U.S. Department of Agriculture cooperating.
